

Warming to 39 °C induces the curated heat-shock core, with or without cGAS

Question — if almost no HSR_core gene is in the set, is the heat-shock response simply absent from the 39 °C response? Answer — no. HSR_core is the strongest of the two lenses in all three contrasts (WT NES +2.05, FDR 1.9e-05; cGAS-KO NES +2.07, FDR 3.4e-05).

NES > 0 means the lens is enriched toward genes higher at 39 °C. Effective set size is printed as n present of n nominal; both lenses are wholly recovered in these rankings. Enrichment of a lens is a separate measurement from that lens being contained in the thresholded set. Claim tier: confirmatory for this temperature contrast; correlative for any fever reading. HSR_core is a curated stress-response reference; read human fever-cause language as unsupported.
