

Ortholog mapping loss: mouse set -> human set

Each bar = the mouse up/down set decomposed by fate; '->N' = resulting human set size.
Gates = fdr_logfc (primary gate) + fdr_only (gate-sensitivity). Red * = > 50% dropped (alarm).

Bar height = mouse-set size; green kept 1:1, orange one->many (each human gets the mouse t). The two drop segments are different statements: grey means the orthology source knew the symbol and had no human counterpart, purple m
