

Warming to 39 °C changes the same genes with and without cGAS — apart from 23

Question — does 39 °C produce a coherent transcriptional response, and does that response require cGAS? Answer — coherent, and largely shared: 23 of 19,679 genes separate the two genotypes, and every one of them lies on the same side of the line.

Each dot is one gene. Both axes are its log2 fold change at 39 versus 37 °C, measured in WT (x) and in cGAS-KO (y).

Δ = that log2 fold change; sig = adj.P < 0.05.

- no detectable difference between genotypes at n=5
- falls with heat in both genotypes, and further without cGAS
- ▲ rises with heat in WT, falls without cGAS
