

Genes changed per comparison (adj.P < 0.05, no fold-change cut-off)

Up and down are relative to the first-named side of each comparison. For the interaction, up = heat response larger in WT than in cGAS-KO. All comparisons share one count scale, so the small ones read as printed numbers rather than visible bars.

Every count on this panel uses adj.P < 0.05 with NO fold-change cut-off. The frozen mouse-to-human projection signature also requires |log2FC| >= 1.0, so it keeps only a few hundred genes per contrast — a stricter gate on the same statistics, not a different result.
