

Observed counts against the depth-matched permutation null, per arm

Each histogram is 2000 draws of a gene set the size of that arm's annotated part, matched to it band by band on how many GO BP terms each gene carries, scored through the same hypergeometric and the same BH adjustment as the arm. The left column counts terms reaching q below 0.05, the right counts drawn genes falling in at least one of them. The triangle marks the median of a uniformly drawn null of the same size, which is the comparison the annotation-depth matching replaces. Seed 20260730.
