

Fig 3r. The same heat-driven genes populate many TFs' regulons -- why none is identifiable

Top-20 heat-MAIN-driving genes of Hif1a's regulon (rows, ordered by signed contribution) x Hif1a + its 12 largest target-sharers (columns, ordered by heat-MAIN ULM score; Hif1a in orange). Filled = the gene is in that TF's CollecTRI regulon. LEFT bar = each gene's heat-MAIN t (all high -> the rows are genuinely heat-driven); TOP bar = each TF's heat-MAIN score (all high -> every column reads as 'active'). Because the same heat-driven genes sit in many regulons, the contrast cannot single out Hif1a -- or any one TF -- as the driver.
