

198 of the 213 genes in WT_heat_up fall in neither curated lens

Question: is the thresholded WT_heat_up set a restatement of either curated lens? Answer: no. Whole-set membership is 12 of 213 in TCR_activation (5.6%), 3 of 213 in HSR_core (1.4%), none in both, and 93% unassigned. This partitions MEMBERSHIP, not rank enrichment.

Membership is counted over the whole arm, never over a leading edge. The unassigned remainder is reported as a remainder: it is not named, and it is evidence for no mechanism. Claim tier: a direct count over frozen sets. HSR_core is a curated stress-response reference; read human fever-cause language as unsupported.
