

Area-proportional membership of the 39 °C-derived up arm and two curated lenses

Circle areas are fitted to the counts; eulerr residual stress = 6.1e-19, diagError = 4.2e-10 (0 = an exact fit).

Bold numbers sit inside the region they count; each callout names an overlap and its leader line points at it. Open circles mark the two overlaps that exist; open diamonds mark the two EMPTY intersections, anchored where the count would sit if it were not zero. Human counterpart after ortholog projection: 2 of 199 WT_heat_up genes fall in the curated HSR core. Conditioning either curated lens on the other moves NES by about +0.005. Set membership only: a lens enriching is a separate measurement from that lens being contained in WT_heat_up. HSR_core is a curated stress-response reference; read human fever-cause language as unsupported.
